CS 70 Fall 2003 — Discrete Mathematics for CS — Wagner — Lecture 14

(More) Secret Sharing, Polynomials, and Error Correcting Codes

Motivation:

Recall we're finding ways to share a secret S among n people such that any k of them can reconstruct S, but any coalition of $k-1$ of them have absolutely no information about what S is.

Galois Fields:

Recall that the Galois Field GF_q is the set of numbers $\forall x \in \mathbf{Z} : \{0 \leq z \langle q\}$ together with the operations $\cdot \pmod q$ and $+ \pmod q$. In this lecture, we will work with polynomials over GF_q.

Definition: r is a root of a polynomial $\Leftrightarrow P(r) = 0$

Recall from the previous lecture:

Theorem: Over any field F, any degree n polynomial has at most n roots. (The proof was given by induction over n.)

Theorem: Given a field with points $(a_1, b_1), \ldots, (a_n, b_n)$, there is a unique polynomial P of degree n-1 such that: $\mathbf{P}(x) : \forall i P(a_i) = b_i$

Example: Consider a polynomial of degree 2 over GF_2, where:

$$P(1) = 2 \qquad (2) = 4 \qquad P(3) = 2$$

$$\Delta_1(x) = \frac{x-2}{1-2} \cdot \frac{x-3}{1-3} \qquad \Delta_2(x) = \frac{x-1}{2-1} \cdot \frac{x-3}{2-3} \qquad \Delta_3(x) = \frac{x-1}{3-1} \cdot \frac{x-2}{3-2}$$

$$P(x) = 2\Delta_1(x) + 4\Delta_2(x) + 2\Delta_3(x)$$

$$\Delta_1(x) = \frac{(x-2)(x-3)}{2}$$

$$2^{-1} \pmod{()7} = 2 \cdot 4 \pmod{()7} \equiv \pmod{()7}$$

Properties of Polynomials:

- A polynomial of degree n has $\leq n$ roots.
- n points define a unique polynomial of degree $n-1$.

Exercise: Consider n points in a finite field GF_q. How many polynomials of degree n pass through these points? $1, 2, q, n, \infty$????

Points	How many degree $n-1$ polynomials.
n	1
$n-1$	q

This is because there are exactly q choices for the value of the polynomial at the n-th point. For each such choice, there is exactly one polynomial of degree $n-1$.

$n-k$	q^k

Back to Secret Sharing:

Given n people, how do we construct a system where:

- Any subset of k out of n can reconstruct s, the secret.
- Any subset of $k-1$ out of n knows *nothing about s.*

Let q be a prime larger than n and s. We will work over GF_q. Let P be a random polynomial of degree $k-1$ such that $P(0) = s$. We can pick P either by picking its coefficients (other than the constant term, which is s) to be random elements of GF_q, or by picking its values at $1,\ldots,k-1$ to be random elements of GF_q:

$$P(1) = r_1 \qquad P(2) = r_2 \qquad \ldots \qquad P(k-1) = r_{k-1}$$

Both methods result in a random polynomial from the same set.

Now each person i, for $1 \leq i \leq n$, gets $P(i)$.

- Any k players know $P(x)$ at k points therefore it is possible to interpolate and uncover the secret polynomial $P(x)$, evaluate it at $P(0) = s$ revealing the secret code s hidden by the polynomial.
- Any $k-1$ players have no information about s, since their $k-1$ values are consistent with any of the q possibilities for $P(0)$ (there is a unique polynomial of degree $k-1$ that goes through the $k-1$ given points and this chosen value at 0). Therefore they have no information about the secret s.

Why must the modulus of the field be prime?

Consider:

$$(\mathbf{Z}_{15}, +, \cdot) \qquad x^2 = 1 \pmod{15}$$

$1, 4, 11, 14$ are roots of the polynomial! More than 2 values is not good. q, the modulus of the field (in this case $q = 15$), must be prime.
